ABSTRACT

The present document deals with the Relap5/Mod3.2 analysis of the small break LOCA experiment BL-44 performed in LOBI/MOD2 facility.

LOBI/MOD2 was a PWR simulator (Integral Test Facility) installed at JRC (Joint Research Center) in Ispra Establishment (I). Volume scaling and core power scaling factors are 1/712, with respect to the KWU Siemens 1300 MWe (3900 MWt) standard reactor.

The experiment is originated by a small break in the cold leg (2" equivalent break area in the plant) without the actuation of the high pressure injection system. Low pressure injection system actuation occurs after core dry-out and accumulators intervention is foreseen when primary pressure falls below 4 MPa.

The Relap5 code has been extensively used at University of Pisa; the nodalization of LOBI facility has been qualified through the application of the version Relap5/Mod2 to the same experiment and another test performed in the same facility.

Sensitivity analyses have been addressed to the influence of several parameters (like discharge break coefficient, time of accumulators start etc.) upon the predicted transient evolution.

Qualitative and quantitative code calculation accuracy evaluation has been performed.

1. INTRODUCTION

The performance assessment and validation of large thermalhydraulic codes and the accuracy evaluation when calculating the safety margins of Light Water Reactors are among the objectives of international research programs, such those organized by the committee on the Safety of Nuclear Installations (CSNI) and the Code Application and Maintenance Program (CAMP).

Solution of these problems would ensure the effectiveness of engineered safety features and, eventually, lead to cost reductions through better design. This activities could also contribute to the determination of a uniform basis on which to assess the consequences of reactor system failures in Nuclear Power Plants, refs. [1] and [2].

The execution of the experiments in Integral Test Facilities simulating the behavior of a nuclear plant, plays an important role in this connection, both considering the system code assessment and the possibilities to identify and characterize the relevant phenomena during off-normal conditions.

A special kind of experiments are the so called counterpart tests. These are similar experiments performed in differently scaled facilities. It is well clear that transient scenarios measured in the experimental rigs can not be directly extrapolated to the plant conditions. Nevertheless one of the objectives of a counterpart test is to evaluate the influence of the geometric dimension of the loop upon the evolution of a given accident.

Counterpart tests have been performed in four PWR simulators: LOBI, SPES, BETHSY and LSTF, ref. [3], respectively available at the European Community Joint Research Center of Ispra (I), at SIET in Piacenza (I), at CENG in Grenoble (F) and at JAERI in Tokai-Mura (J). The selected experiment is a small break LOCA originated by a rupture in the cold leg, without actuation of high pressure injection system and with accumulators availability, in particular, starting from low power conditions (about 10% of the nominal period). Both tests have been performed in the smallest facilities, SPES and LOBI, starting from full power conditions, all other conditions being the same.

The activity documented in this report is a part of a multipurpose research aiming at the overall evaluation and exploitation of the counterpart test database. On one hand the Relap5 system code (Mod2 and, presently, Mod3.2) has been applied to the post test analysis of the four experiments and to the evaluation of plant scenario during the same transient; on the other hand the experimental data base have been evaluated to demonstrate the similarity in the behavior of the facilities, ref. [3]. The two parts of the research have been merged and conclusions have been drawn in relation to the scaling of phenomena and of the accuracy of thermalhydraulic code calculations.

Previous reports dealt with the evaluation of the experimental data base constituted by the four counterpart experiments (ref. [4]) and with the qualification of Relap5/Mod2 nodalization used for the post test analyses, ref. [5], as well as with a complete evaluation of the data base leading to the evaluation of uncertainties (e.g. ref. [6]).

The present document deals with the post test analysis performed by Relap5/Mod3.2 of the high power small break LOCA counterpart test carried out in LOBI/MOD2 facility (BL-44), ref. [7].

The main objective of the high power test was to evaluate the influence of initial conditions (particularly, high power, high mass flow rate and low steam generators pressure) upon the evolution of the mentioned Small Break LOCA Transient.

The purpose of this report is to evaluate the performance of the Relap5/Mod3.2 in comparison with the previous application with the version Mod2. In order to achieve this, a systematic qualitative and quantitative accuracy evaluation has been performed. The quantitative analysis has been performed adopting a method (ref. [8],) developed at DCMN, which has capabilities in quantifying the errors in code predictions related to the measured experimental signal; the Fast Fourier Transform (FFT) is used aiming to have an integral representation of the code calculation discrepancies (i.e. error between measured and calculated time trends) in the frequency domain.

2. DESCRIPTION OF THE EXPERIMENT

2.1 LOBI facility

The LOBI-MOD2 facility is a high pressure integral system test facility simulating the geometrical and operating configuration of a four-loops 1300 MWe PWR. More in particular, it reproduces the KWU PWR plant installed at Biblis (Germany).

This facility was designed, released and operated at the Joint Research Centre (JRC) of Ispra Establishment, and it was one of the largest high pressure integral systems of this kind operating in Europe.

A sketch of the primary circuit of the facility is reported in Fig. 1. It essentially consists of the following parts (refs. [9] and [10]):

- a pressure vessel containing the heated bundle consisting of 64 directly heated rods arranged in 8x8 square matrix. A cosine shaped axial power profile is obtained trough seven different thickness of the hollow cylinder simulating the rods. Nominal heating power is 5.3 MW. Four bypass flow paths are realized in the vessel region: three between upper plenum and downcomer and one between lower plenum and upper plenum. The ones between upper plenum and downcomer are obtained via gap in the connection hot leg-vessel, via "ad hoc" holes in the barrel and via the upper head, respectively;
- a small vessel simulating the upper head of the PWR vessel;
- two loops, respectively called "INTACT" loop and "BROKEN" loop, the former representing the three unbroken loops of the four-loops reference PWR plant, the latter simulating "broken" loop in which pipe ruptures of various sizes can be mounted at different locations. The two loops are equipped with equal recirculation pumps which, during steady-state, run at different velocities to achieve rightly scaled flow rates. In each loop a steam generator is containing components such as inverted U-tubes, an annular downcomer and coarse and fine steam separators modeling the geometry of the reference plant. The exchanged power in the two steam generators, at the nominal operating conditions, is of 1.32 MW (8 U-tubes) and of 3.96 MW (24 U-tubes) for the BROKEN and the INTACT loop, respectively;
- an active secondary loop system, shown in Fig. 2, containing two condensers simulating the reactor turbines, the feed water pump and the auxiliary feedwater system;
- a pressurizer and surge line connectable to either the intact or broken loop;
- emergency core cooling system equipped with active High Pressure Injection System with up to 4 HPIS injection pumps, Low Pressure Injection System and a Passive Accumulator System, with two accumulators, one in each loop.

The scaling criteria utilized in the LOBI-MOD2 facility led to the following characteristics:

- volume, primary circuit coolant mass flow and power input are scaled down from the referred reactor values, by a factor of 712;
- in order to preserve the gravitational head the absolute heights and relative elevations of the individual system components have been kept at reactor values with the exception of the pressurizer, which is shorter in order to preserve the scaling ratio and maintain, at the same time, an acceptable flow area.

The LOBI test facility was initially designed to simulate the thermalhydraulic scenario in a Pressurized Water Reactor during Large Break Loss-of Coolant Accident (LBLOCA). Subsequent modifications to the original LOBI/MOD1 facility, like a more accurate design of the secondary side of steam generators, a new reactor pressure vessel and a greater number of thermocouples installed, made LOBI/MOD2 well faced for simulation of a wide variety of Small Break LOCA (SBLOCA) and special transients experiments.

The instrumentation system of the facility allowed the measurements of the main thermalhydraulic parameters performed at the boundaries of the principal loop components and at the principal sections of the pressure vessel and the steam generators.

The main measurement locations in the facility can be classified as follows:

- Loop pipes: performed within "measurement inserts" which contain the complete instrumentation for each location. The "insert" can be "simple" or "complete". In the simple insert the measurement of fluid and wall temperatures and absolute and differential pressure are performed. The complete inserts also contain flow and density measurement devices. A distinction, in the instrumentation available in the inserts, is made between vertical and horizontal pipes: the inserts for horizontal flow are supplied with double instrumentation for temperature and flow measurement in order to show eventual stratification phenomena in the pipe section.
- Reactor pressure vessel simulator: with absolute pressure taken in the upper plenum. Differential pressure measurements are provided over all the main sections along the flow path of the pressure vessel. Mass flow information is provided by flow and density measurements in the core inlet box. A second density measurement indicates voiding of the lower plenum. Fluid and wall temperatures are measured in the more representative locations in the vessel.
- Heater rod bundle: each heater rod is supplied with three thermocouples in the tube wall.
- Steam generators: measurements are provided of fluid temperatures, U-tubes wall temperatures and differential pressure on the primary and secondary side.
- Pressurizer: fluid temperatures and pressure are measured and the surge line flow is obtained by a full flow turbine. Differential pressure is measured over the surge line and over the height of the pressurizer to monitor the filling level.

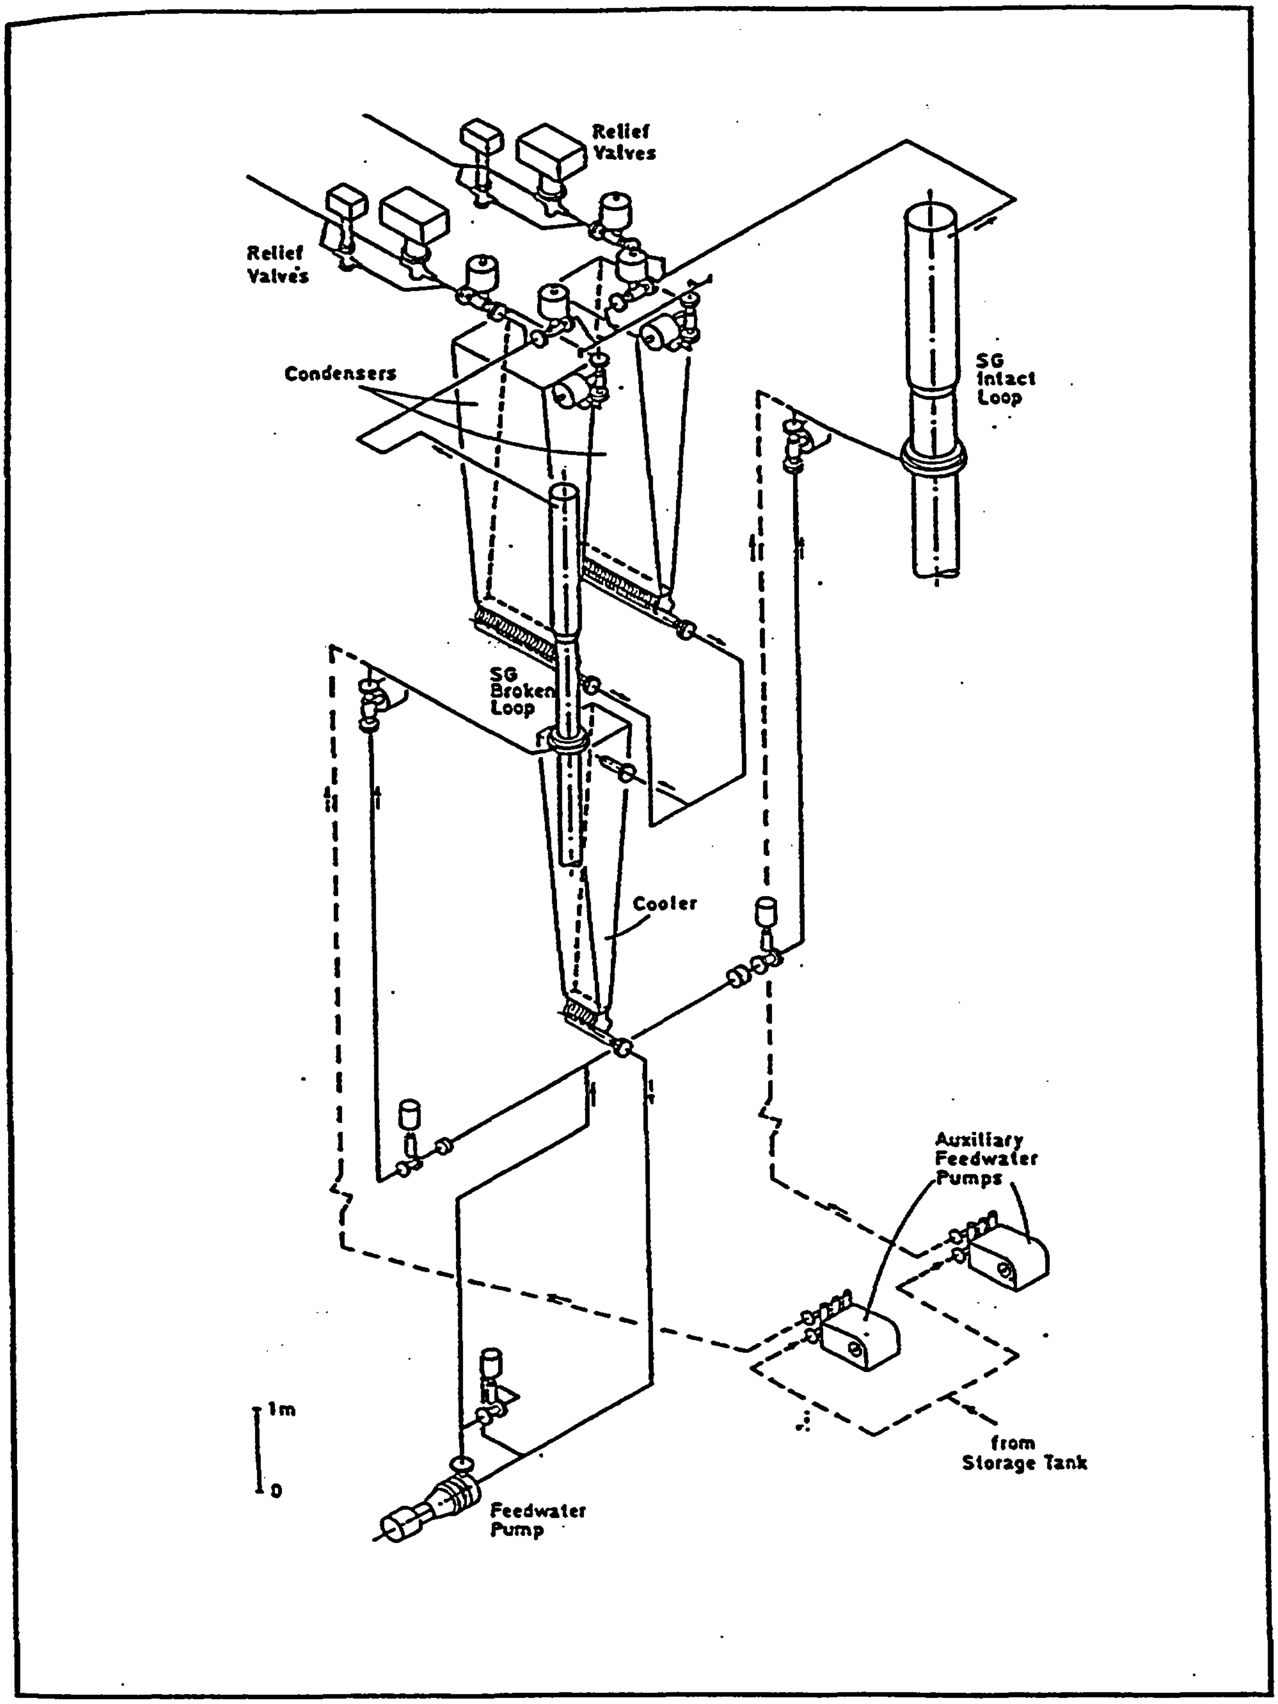

Fig. 2: LOBI/MOD2 facility - secondary circuit

2.2 Test BL-44

The counterpart test is essentially a Small Break LOCA originated by a rupture in the cold leg between the pump and the reactor vessel. The break is "side oriented" in the pipe and has an area equivalent, roughly, to 6 % of the main pipe area: the reference break diameter in the prototype plant is 50 mm (2 "). The sequence of interventions of the various systems is typical of this kind of transient in a plant: after the break occurrence, scram and pumps trip are provided, together with a signal for isolating steam generators (feed water and steam line closure). Accumulators intervention is foreseen when primary pressure below 4 MPa. After the accumulators emptying, the flow rate from the break causes mass depletion from the primary system, leading unavoidably to core dryout. Low pressure injection system actuation is foreseen after the occurrence of core dryout and is effective in rewetting the rods

It should be noted that, owing to limitations in maximum power available in Bethsy and Lstf, the initial conditions of the four experiments have been established at a core power around 10 % of the reference reactor nominal power. Few relevant initial condition values are given in Tab. 1.

As already mentioned, in Spes and Lobi facilities the counterpart experiments have been repeated utilizing the full power, in order to evaluate whether the transient evolution was affected by the initial conditions.

The data given in Tab. 1 demonstrate that, in the four low power experiments, the choice was made to preserve the initial value of the fluid temperature jump across the core (mass flow rate reduced of the same amount as power) and to have the same hot leg temperature. In order to achieve this, it was necessary to increase the initial temperature and pressure of steam generators with respect to the nominal conditions.

The general purpose of the counterpart experiments (including the two full power experiments) was to be part of the counterpart program. Relevant thermalhydraulic phenomena of potential interest during the experiments are: mass distribution in the primary system, heat transfer with secondary side with degraded primary conditions, including reversal of heat flux, loop seal behavior, core heat-up and rewet, accumulators performance and stratification in horizontal pipes.

The transient setpoints imposed and resulting sequence of events for LOBI BL-44 test is reported in Tabs. 2 and 3. The transient scenario can be derived from Figs. 3 and 4. In this test (as well as in BL-34 experiment), the pressurizer is connected to the broken loop, because, as already mentioned, the test is a counterpart of experiments performed in Lstf, Bethsy and Spes facilities where this configuration was adopted.

The accident can be subdivided into four main periods from a phenomenological point of view:

a) subcooled blowdown and first core dryout rewet (time from 0 to 204 s);
b) saturated blowdown and primary to secondary side pressure decoupling (from 204 s up to accumulators emptying);
c) mass depletion in the primary loop (from accumulators emptying to the final core dryout);
d) intervention of low pressure injection system that quenches the core.

Phase a). Following the break the primary system pressure is subject to an initial fast decrease (0.1 MPa/s) up to the achievement of saturation conditions upstream the break; this occurs at about 80 s into the transient. The sharp initial pressure decrease lead to scram, main coolant pump trip and isolation of steam generators in the first 10 s of the transient. Pressurizer emptying occurs in about 25 seconds. During the phase a), U-tubes draining occurs in primary side (at about 90 s) for the loss of natural circulation between core and downcomer through the steam generators: at this time the saturation temperature in the primary loop is still few degrees higher than saturation temperature in the secondary side.

The stop in natural circulation, essentially due to voiding and mass depletion in the upper zones of the loop, causes manometer type situation in the primary loop piping: the steam produced in the core partly flows directly in the break through the bypass and partly pushes down the level in the core, to balance the liquid level present in loop seals. In this situation core dryout occurs at about 189 s in the top level of the rods.

The loop seal clearing is present only in the intact loop (at about 197 s): pumps operation mode and, particularly, the switch on of the pump locked rotor simulator valve in the broken loop only, may be at the origin of the different behaviour of the two loops. Timing of occurrence of the phenomena are different in BL-34 and BL-44 tests and justify their difference as far as the loop seal clearing in broken and intact loop is concerned.

Phase b). Continuous core boil off and primary-to-secondary side pressure decoupling characterize the first part of phase b). The core boil off (produced steam flows almost entirely to the break) causes a second dryout at about 370 s at a pressure higher than the accumulators pressure (4 MPa); liquid level hold up in the broken loop seal occurs, starting from about 200 s, somewhat limiting steam flow to the break. Probably the reverse speed of the pump (at -28 rpm during the whole transient) contributes to the formation of liquid hold up in the broken loop seal, pump side. In this period the heat transfer from secondary side to primary side is quite small compared with core power, because the high void fraction in the U-tubes.

The accumulators intervention at 428 s causes the recovery of liquid level in the core and a second rewet that is completed at about 551 s. The isolation of accumulators occurs at about 960 s: in the period from 428 to 960 s the primary system mass increases, because the liquid flow rate delivered by accumulators is larger than the break flow rate.

Phase c). The stop of accumulators injection (t = 964 s) causes another mass depletion period, leading to the third dryout at about 1711 s into the transient, when the primary pressure was around 1 MPa. No other significant event occurs in this period, excluding the core level depression. When the rods surface temperature reaches 800 K, the low pressure injection system is actuated (2066 s) in the intact loop cold leg.

Phase d).The LPIS flow rate (0.4 kg/s) is quite effective in causing the third core quench and in recovering the facility. The quench front velocity is larger than 0.02 m/s and, at about 2200 s, the core is completely recovered. Core refill occurs in this period. The test was terminated at 2350 s, with pressure around 0.55 MPa.

3. ADOPTED CODE AND NODALIZATION

3.1 Relap5/Mod3.2 code

The light water reactor transient analysis code, RELAP5, was developed at the Idaho National Engineering Laboratory (INEL) for the U.S. Nuclear Regulatory Commission (NRC). Specific applications of the code have included simulations of transients in LWR system such as loss of coolant, anticipated transients without Scram (ATWS) and operational transients, such as loss of feed water, loss of offsite power, station blackout and turbine trip.

The Mod3 version of RELAP5 has been still developed by the INEL, but a consortium consisted of several countries and domestic Organizations that were members of the International Code Assessment and Application Program (ICAP) and its successor organization, Code Application and Maintenance Program (CAMP), contributed to the development and the validation process.

RELAP5/Mod3.2 code, refs. [11] and [12], is based on a non-homogeneous, non-equilibrium set of six partial derivative balance equations for the steam and the liquid phase. A non-condensable component in the steam phase and a non-volatile component (boron) in the liquid phase can be treated by the code. A fast, partially implicit numeric scheme is used to solve the equations inside control volumes connected by junctions.

In particular, the control volume has a direction associated with it that is positive from the inlet to the outlet. The fluid scalar properties, such as pressure, energy, density and void fraction, are represented by the average fluid condition and are viewed as being located at the control volume center. The fluid vector properties, i.e. velocities, are located at the junctions and are associated with mass and energy flow between control volumes. Control volumes are connected in series using junctions to represents flow paths.

Heat flow paths are also modeled in a one-dimensional sense, using a staggered mesh to calculate temperatures and heat flux vectors. The heat structure is thermally connected to the hydrodynamic control volumes through heat flux that is calculated using a boiling heat transfer formulation. The heat structures are used to simulate pipe walls, heater elements, nuclear fuel pills and heat exchanger surfaces.

Several new models, improvements to existing models and user conveniences have been added. The new models include:

- the Bankoff counter-current flow limiting correlation;
- the ECCMIX component for modeling of the mixing of the subcooled emergency core cooling system liquid and resulting interfacial condensation;
- a zirconium-water reaction model to model the exothermic energy production on the surface of zirconium cladding material at high temperature;
- a surface to surface radiation heat transfer model with multiple radiation enclosures defined through user input;
- a thermal stratification model.

3.2 General criteria adopted for the code models

A detailed nodalization reproducing each geometrical zone of the loop has been developed: in principle it is suitable for different types of transients.

The general methodology followed is described in refs. [12] and [13]. Being used, in this case, the Relap5/Mod3 code, great care is given to the information contained in the specific user manual.

Nevertheless, it should be noted that this information alone is generally not exhaustive for the development of an adequate set of input data. So, few supplementary criteria, to those reported in the manual, have been fixed, as result of experience, in the attempt to set up a "homogeneous" nodalization, that is to avoid imbalance in the distribution of hydraulic and thermal meshes. Of course, the achievement of this objective, requires a good user knowledge of the reference facility characteristics. Moreover, the prevision of the phenomena to be simulated in the calculation can also have a role in this context. Compromises apply in the choice of number of nodes: on the one hand there is the need to develop a model adherent to the geometric and material particularities of the physical system, on the other hand computer capabilities (essentially CPU time) limit the maximum number of nodes.

Two limits have been fixed for the linear dimension of nodes: all the volumes should have their flow lengths comprised between 0.5 and 1.0 m (with the exception of core stack, much more detailed, of the descending zone of the SG U-tubes and of the pressurizer and accumulator surge lines, nodalized by 2.0 m length nodes). With regard to conduction heat transfer, the distance between neighboring mesh points inside structures must be less than 5 mm in each case, up to the lower limit of few tenths of mm used for heated rods and steam generator U-tubes. In the subdivision of volumes and slabs the position of instrumentation has been considered.

The following choices have been made with regard to code options:

- thermodynamic non-equilibrium is allowed in all control volumes;
- the smooth area change for all the junctions where it is allowed (i.e. excluding the motor valves);
- the stratification option is used in the junctions of the hot legs and cold legs horizontal parts.

3.3 LOBI/MOD2 nodalization description

The LOBI/MOD2 nodalization is shown in Fig. 5. The correspondence between the zones of the facility and the nodes of the code model are exposed in Tab. 4. In this table the facility is divided in general zones, composed by single components, reported in the table according to flow paths in nominal conditions. The number and the type of the hydraulic nodes, corresponding at each single component of the facility, are indicated in the table itself.

Hereafter some significant aspects of the nodalization development are summarized.

Primary system model

The vessel model consists of 29 hydraulic components which are connected through 48 junctions.

The heat structures utilized in the RPV model are made up of 47 heat slabs, distinguished in:

- 13 active structures for the heaters;
- 30 heat slabs for the vessel wall;
- 4 internal non-active structures.

In the vessel model all the bypass flow paths, reported in the facility description, have been modeled:

- bypass from downcomer top to upper plenum via holes simulated by junctions 430-02 (bypass flow rate equal to 0.35 kg/s);
- bypass from downcomer top to upper plenum via gap in the connections with the hot legs simulated by junctions 500-03 and 700-03 (bypass area strictly dependent by thermal expansion of the structures, thus the bypass flow rate valuable, with a large uncertainty band, roughly equal to 1 kg/s):
- bypass from downcomer top to upper head simulated by node 440-01 with bypass flow rate roughly equating to 0.3 kg/s.

Both the broken and the intact loop represent with geometrical fidelity the real hydraulic configuration of the experimental facility. Notwithstanding this, the degree of detail is properly increased in the BL, where are localized, in transient conditions, the most important thermalhydraulic phenomena.

Intact and broken loop are so simulated:

- 53 nodes and 54 junctions for the IL;
- 55 nodes and 57 junctions for the BL.

The accumulators are schematized in both loops and are connected to the respective cold legs.

The localized pressure drops, due to the "locked rotor resistance simulator" is introduced in the loop by the *motor valve* 747 component.

The *time dependent volumes* 742, 603 and 602, connected with the primary system through the *time dependent junctions* 744, 601 and 604 respectively, simulate the pump cooling system. Each system is realized with cold water injection in the pump and consequent water draining from the lower plenum.

Two additional systems can be noted in the pressurizer nodalization:

- a *time dependent volume* and related valve (components 541 and 542);
- a *time dependent junction* and related *time dependent volume (*components 531 and 534).

Both are control systems. The former system allows the primary side pressure to remain constant in a steady-state period. The latter system maintains at an assigned value the liquid level inside the pressurizer. The temperature of the fluid possibly injected by this system corresponds to the saturation conditions inside the pressurizer. A check has been made to verify that the flow rates and the energy exchanged between this system and the primary circuit are well below the reference flow rate and energy values of the primary side. Finally the black structures inside the pressurizer model represents the internal heaters.

Secondary system

The secondary side nodalizations of the two steam generators are very similar, both concerning the hardware of the facility and the control systems (23 nodes, 23 junctions and 45 heat slabs).

Four zones can be recognized in each steam generator:

1) the downcomer, consisting of a single stack of nodes that simulates a multitubular geometry;
2) the riser zone, essentially including the U-tubes;
3) the top of the vessel, including the separator, the dryer and the steam dome regions;
4) the steam line downstream the dome of each SG is simulated with a *time dependent volume* (829 for IL and 929 for BL) connected to the dome by a *time dependent junction* (828 for IL and 928 for BL).

The degree of detail of the nodalization is commensurate to what considered in the primary loop. In particular, the heights of the riser volumes are the same as the minimum between the heights of the rising and the descending corresponding nodes of the primary side U-tubes.

The components 815-01 for IL and 915 for BL simulates the separators in the secondary sides that are necessary in the code model in order to achieve quality equal to 1 in the steam domes.

A relatively large number of control volumes are connected with the steam generators; the following functions are accomplished:

- feed water injection: *time dependent volumes* 832 (IL) and 932 (BL); *time dependent junctions* 833 (IL) and 933 (BL);
- AFW injection: *time dependent volumes* 836 (IL) and 936 (BL); *time dependent junctions* 837 (IL) and 937 (BL);
- safety system: *time dependent volumes* 826 (IL) and 926 (BL), simulating the safety tanks; *trip valves* 825 (IL) and 925 (BL), simulating the safety valves;
- components 824-01 and 823, for IL, and 924-01 and 923, for BL, simulate the control system that assures constant pressure during a steady state period.

The geometrical features of the piping and system connected with SGs are not simulated (e.g. feed water lines, pre-heaters, steam lines - including condenser - etc.), because this is not relevant for the prediction of the transients of interest.

The utilized code resources for the LOBI/MOD2 nodalization are summarized in Tab. 5. In particular, the number of hydraulic components and of the heat structures are here reported.

Tab. 5: Relap5/Mod3.2 LOBI nodalization - overview of code resources

3.4 Nodalization qualification

A nodalization representing an actual system (Integral Test Facility or plant) can be considered qualified when:

- it has a geometrical fidelity with the involved system;
- it reproduces the measured nominal steady state condition of the system;
- it shows a satisfactory behavior in time dependent conditions.

Taking into account these statements, a standard procedure to obtain a "qualified nodalization" has been defined, ref. [14].

The qualification process consists of two main phases:

1) **steady state level:** the nodalization is qualified against data available from nominal stationary conditions measured in the simulated system. To this aim:
   a) relevant geometrical parameters of the facility (e.g. volume, heat transfer area, elevations, pressure drops distribution etc.) are compared with the input data and the differences among them must be acceptably small. The adopted acceptability criteria are reported in the first part of Tab. 6 (see also Fig. 6);
   b) the nominal steady state conditions are simulated with a code running (a hundred seconds time interval is considered acceptable to reach correct steady state values); significant parameters are selected and compared with the measured results. A parameter is considered as significant when it is of major relevance in determining the plant behavior and can be reliably measured. The adopted acceptability criteria for this step are reported in the second part of Tab. 6 (see also Fig. 7).
2) **transient level**: the nodalization is tested in time-dependent conditions reproducing the available experimental transients. This phase also includes the procedure for the qualitative and the quantitative (through the application of the FFT based method) evaluation of the code accuracy, necessary to demonstrate the acceptability of the code transient performance. The demonstration of the quality of the nodalization at the transient level, before application to the reference calculation (BL-44 in this case), involves at least one among the following steps:
   a) perform a "K_v scaled" calculation aiming at the comparison between the nodalization performance and experimental data in another facility (proper scaling factors must be adopted to fix initial and boundary conditions);
   b) compare results of the nodalization with experimental data different than those object of the reference calculations (these can be operational transient data in the case of a Nuclear Power Plant);
   c) compare the results of the nodalization with calculations data coming from a previously qualified nodalization.

The idea of the "Kv-scaled calculation" (item a) comes from the objective to comparing calculated data with experimental data before adopting any nodalizations (i.e. including NPP nodalization) for any kind of calculation (code assessment, licensing, etc.). In this frame, adopting proper scaling criteria (time preventing, volume/power scaling)a comparison can be made between predicted and experimental data in the area of PWR and BWR. This must be used to detect nodalizations and user choice inadequacies. Correction of errors or deficiencies leads to a "on transient" qualified nodalization ready to be used for other purposes.

The acceptability constraints for the FFT (i. e. 0.4 for Average Accuracy and 0.1 for the primary pressure) must be fulfilled in any case.

The qualification process, summarized above, has been applied to the nodalization of Lobi facility.

As concerns the first phase (steady state level), the steady state acceptability criteria previously defined (reported in Tab. 6) have been verified; in particular, the comparison between the calculated and the measured volume vs. height curve and the distribution of pressure drops along the length are reported in Figs. 6 and 7, respectively.

The second part of the qualification process (transient level) has been conducted through the step b) and c) described above: in the first case the International Standard Problem 18, ref. [15], has been in considered, while in the second case the previous simulation with the version Relap5/Mod2, ref. [5], has been utilized (see also below).

It is to be mentioned that the application of the FFT based methodology has been exhaustively performed in the Relap5/Mod2 simulation of BL-44 [16] and it was not repeated in a systematic way for the Relap5/Mod3.2 simulation. No important differences related to any of the finding of the Relap5/Mod2 analyses are expected.

	QUANTITY	ACCEPTABLE ERROR (°)
1	Primary circuit volume	1 %
2	Secondary circuit volume	2 %
3	Non-active structures heat transfer area (overall)	10 %
4	Active structures heat transfer area (overall)	0.1 %
5	Non-active structures heat transfer volume (overall)	14 %
6	Active structures heat transfer volume (overall)	0.2 %
7	Volume vs. height curve (i.e. "local" primary and secondary circuit volume)	10 %
8	Component relative elevation	0.01 m
9	Axial and radial power distribution (°°)	1 %
10	Flow area of components like valves, pumps orifices	1 %
11	Generic flow area	10 %
(*)		
12	Primary circuit power balance	2 %
13	Secondary circuit power balance	2 %
14	Absolute pressure (PRZ, SG, ACC)	0.1 %
15	Fluid temperature	0.5 % (**)
16	Rod surface temperature	10 K
17	Pump velocity	1 %
18	Heat losses	10 %
19	Local pressure drops	10 % (^)
20	Mass inventory in primary circuit	2 % (^^)
21	Mass inventory in secondary circuit	5 % (^^)
22	Flow rates (primary and secondary circuit)	2 %
23	Bypass mass flow rates	10 %
24	Pressurizer level (collapsed)	0.05 m
25	Secondary side or downcomer level	0.1 m (^^)

(°) The % error is defined as the ratio $\frac{|\text{reference or measured value - calculated value}|}{|\text{reference or measured value}|}$

The "dimensional error" is the numerator of the above expression

(°°) Additional consideration needed

(*) With reference to each of the quantities below, following a one hundred s "transient-steady-state" calculation, the solution must be stable with an inherent drift < 1% / 100 s.

(**) And consistent with power error

(^) Of the difference between maximum and minimum pressure in the loop.

(^^) And consistent with other errors.

Tab. 6 - Criteria for nodalization qualification at the steady-state level.

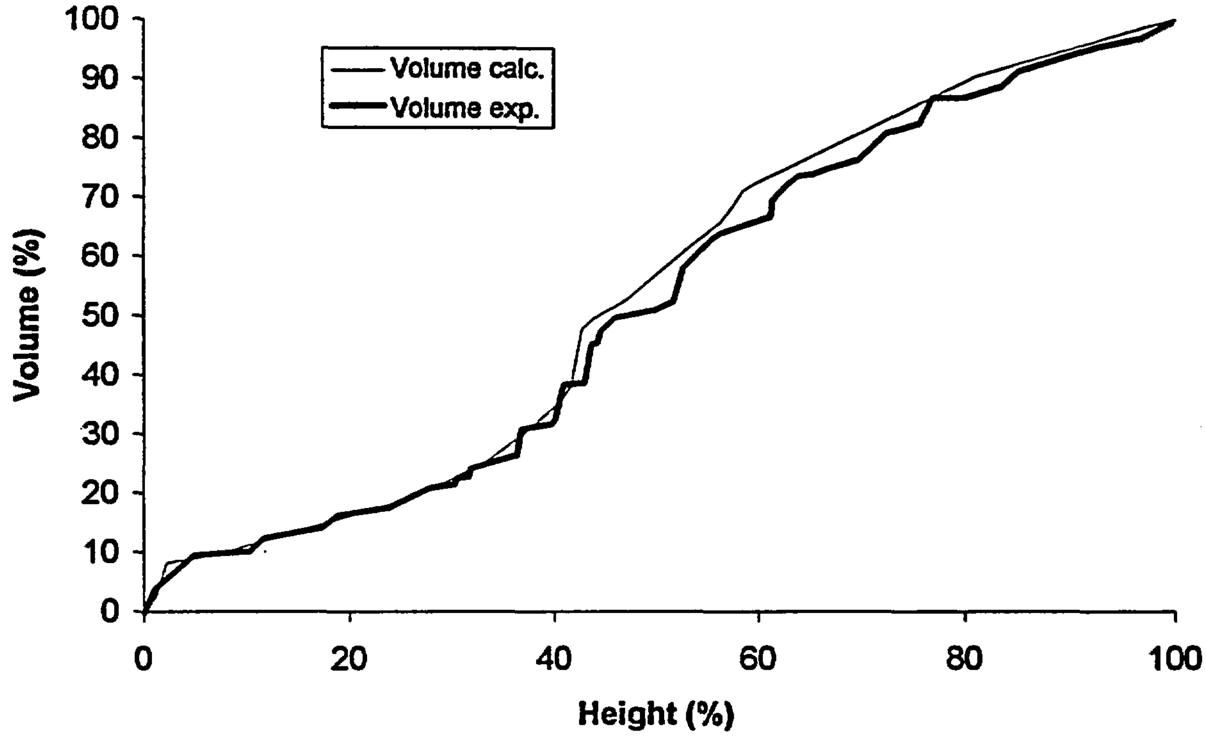

Fig. 6: Comparison between measured and calculated volume vs. height curve

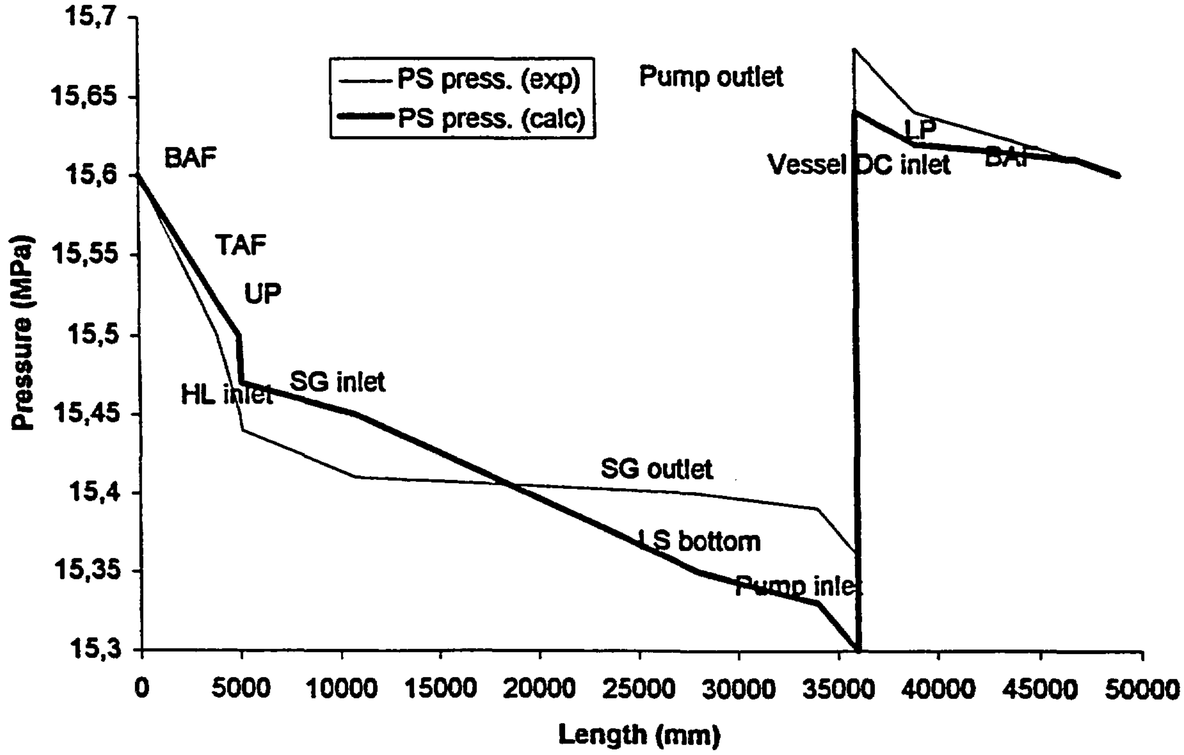

Fig. 7: Comparison between measured and calculated DP vs. length curve

4. ANALYSIS OF POST-TEST CALCULATION RESULTS

Three main calculation types can be distinguished in a meaningful code assessment process:
a) 100 s steady state;
b) reference calculation results;
c) results from sensitivity studies.

It may be noted that item a) may constitute a part of the nodalization qualification process, described in the previous chapter; however, the fulfillment of criteria reported in Tab. 6 is necessary each time a new experiment is considered and before starting transient calculations by using the previously qualified nodalization.

The reference calculation results, item b), must outcome from the qualified nodalization and satisfy qualitative and quantitative accuracy related criteria. The reference calculation is not "the best" calculation achievable by the code. In order to get the reference calculation, boundary and initial conditions of the considered experiment (i.e. input data for the reference calculation) may be changed within their uncertainty ranges; if a user choice is introduced (e.g. changes in noding detail), its validity and acceptability must be checked by repeating the nodalization qualification process.

Sensitivity analyses, item c), must be carried out to demonstrate the robustness of the calculation, to characterize the reasons for possible discrepancies between measured and calculated trends that appear in the reference calculation, to optimize code results and user option choices, to improve the knowledge of the code by the user.

The attention is focused hereafter toward the analysis of the reference calculation results, item b), considering that steady state calculation, item a), is part of the nodalization qualification process and sensitivity analyses, item c), can be designed following the analyses at the previous step. Typical results are provided in relation to the three steps.

When calculating the quantitative accuracy, twenty-one time trends have been selected in relation to which experimental data exist: these are assumed to be the minimum number of measured quantities that fully describe the experimental scenario. The related list is given in the first column of Tabs. 11 and 13.

When calculating qualitative accuracy, including the comparison between time trends, reference is made to the same list (e.g. Apps. 1 and 2) of Tab. 13; the following quantities have been added to the comparison: pressure drop across DC-UH bypass, pressure drop in the U-tubes ascending leg (also a measure of liquid hold-up in the U-tubes), core inlet flow rate, pressure drop in cold leg, mass flow rate in SG downcomer, hot leg mass flow rate. Fig. 29 has been added to give an overall view of the system performance (primary and secondary pressure together).

4.1 Steady State calculations

A steady state calculation, by running the code with the 'TRANSNT' (transient) option for 100 s has been completed. This constitutes the final step of the nodalization qualification process at steady state level.

The related results are shown in Tab. 7 and in App. 1. In both cases, resulting values are compared with experimental data. In the case of Tab. 7, for completeness, the data calculated by Relap5/mod2 are included as taken from ref. [5].

It may be noted that the data in Tab. 7 deal with most of the parameters imposed for the nodalization qualification process (Tab. 6): the values in the table have been taken from the code output at 100. s. The time trends above identified are part of the App. 1, numbering of figures is different owing to the obvious lack of time trends dealing with ECC and break flow rates.

The analysis of data brings to the following conclusions:

- the criteria for nodalization qualification are fulfilled, though the complete comparison between data in Tab. 7 and in App. 1 with acceptability criteria has not been done owing to the lack of experimental data; in addition, some of the criteria can be matched by considering sums or combinations of values from Tab. 7 (e.g. the primary circuit power balance can be obtained by considering data at items 1, 4, 14, 16 and 17); still, the error on bypass flow rate, can be better seen by considering the errors in fluid temperatures owing to the fact that the direct experimental information about bypass flow rate is uncertain (measurement error not available);
- the calculated values are stable as it results from Figs. 1 to 26;
- differences between Relap5/mod2 and Relap5/mod3.2 codes results are negligible;
- discrepancies between measured and calculated values of heater rod temperatures, come from the position of thermocouples and from generic experimental error (the calculation result refer to the surface, the experimental data are taken slightly inside the surface, the error almost disappears at low linear rod power, during the transient);
- discrepancies in the case of accumulators pressure, primary side mass and vessel riser level, are within the acceptability criteria, considering the experimental uncertainties (about ± 0.1 MPa for accumulators pressure and ± 3 %for primary mass);
- the discrepancy in the cases of pressure drops is attributed to the experimental error and to the position of the measurement pressure taps not accounted for by the calculated results;
- the discrepancy related to the recirculation mass flow rate in the steam generator, can also be originated by a measurement error; however, in this case tuning or adjustments of steady state code results was considered unnecessary owing to the low influence that this parameter has in the selected transient (early main coolant pump and feedwater trips occur).

4.2 Reference calculation results

The post-test calculation was performed starting from the input deck suitable for Relap5/Mod2. A 'blind' post test was performed by Relap5/Mod3.2 constituting the reference calculation for this study (label B44E); the related time trends and significant single valued parameters are reported, together with experimental data, in App. 2 and in Tab. 8, respectively.

A comprehensive comparison between measured and calculated trends or values was performed, including the following steps:

a) comparison between experimental and calculated time trends on the basis of the 29 variables introduced above (App. 2);
b) comparison between values of quantities characterizing the sequence of resulting events, Tab. 8;
c) qualitative evaluation of calculation accuracy on the basis of the phenomena included in the CSNI matrix, ref. [17], as given in Tab. 9;
d) qualitative evaluation of calculation accuracy on the basis of the Relevant Thermalhydraulic Aspects (RTA, also used for code uncertainty derivation, e.g. ref. [6]), as given in Tab. 10;
e) quantitative evaluation of calculation accuracy, utilizing the FFT based method (FFTBM), described in refs. [8] and [16], see also App. 1 in ref.[20], as given in Tab. 11.

Comments related to items a) and b) are given below, distinguishing groups of homogeneous variables, while the discussion about items c), d) and e) is given in sect. 4.2.1.

Absolute Pressures

The primary system pressure is quite well predicted by the code and the phenomenological phases (e.g. subcooled blowdown, saturated blowdown and steam flow from the break) can be easily recognized from the calculated time trend (Fig. 8 below and Fig. 1 in App. 2). During the saturated blowdown (from about 50 s up to 500 s) the calculated pressure is higher than the experimental one. This discrepancy is connected with the overestimation of the secondary side pressure (Fig. 2 of App. 2): heat losses to the environment appear to have a substantial role in this case.

The accumulator generally follows the primary pressure; time of accumulator actuation is reasonably well predicted, together with the time accumulator stop.

Fluid temperatures

Measured and calculated fluid temperatures are compared in Figs. 4, 5, 6, and 8 of App. 2, the last one related to the steam generator and the other ones related to the primary circuit.

Core inlet and outlet fluid temperatures are qualitatively well predicted (Figs. 4 and 5). The predicted core outlet fluid temperature presents two peaks in correspondence to the two core level depressions. The superheating is larger than in the experiment and the position of the thermocouple strongly affects this time trend. This is specifically true for the upper head fluid temperature where a very high superheating is measured; in this case, it seems evident that the thermocouple gives a measure of the structural mass temperature starting from about 400 s into the transient, i.e. following the emptying of the upper head.

Mass flow rates and residual mass

The measured values of break flow rate (Fig. 9 below and Figs. 7 and 9 in App. 2), the ECCS flow rate (Fig. 10 below and Fig. 10 in App. 2), core inlet (Fig. 25 in App. 2), hot leg mass flow rate (Fig. 28 in App. 2) and the steam generator downcomer flow rate (Fig. 27 in App. 2) are compared with the respective calculated trends.

Break flow rate is well predicted; up to 500 s into the transient it is slightly underpredicted, but the related error can be considered within the uncertainty bands.

The calculated ECCS flow rate is in a good agreement with the calculated trend; it can be noted the overprediction of the flow rate delivered by accumulators and the delay of the LPIS intervention, due to the delayed occurrence of the third dry out.

The residual mass in primary side is well predicted (Fig. 14 of App. 2); the calculated value is higher than the experimental one for all the transient, but the difference can be considered within the experimental uncertainty band.

Pressure drops

Pressure drops between different points of the primary circuit are considered in the comparison, e.g. Figs. 17, 19, 20, 22, 23, 24 and 26 in App. 2. All of the comparisons, with different extent, suffer of the limitation already explained in sect. 4.1 (pressure taps not coincident with the center of the volumes of the nodalization).

Pressure drop in the intact loop is reasonably well predicted by the code; this is not the case for the broken loop, because the code predicts the occurrence of loop seal clearing (not occurred in the experiment) at about 60 s. This confirms the difficulty, already emphasized in previous analyses [ref. 5] in correctly predicting a critical phenomenon like loop seal clearing. The distribution of pressure drops in the initial steady state, both direct and reverse (in this last case calculated data can not be qualified), are responsible for the misprediction of loop seal clearing phenomena. This is a well known limitation, resulting from several code applications to SBLOCA analyses and in all the cases assessed by the present authors it does not affect the code capability in predicting the overall transient scenario.

In the case of steam generator inlet plenum to U-tubes top and downcomer to upper head bypass, the pressure drops are very well predicted by the code.

Levels

The pressurizer level (Fig. 11 below and Fig. 21 in App. 2) is well predicted in the calculation, testifying the good prediction of the subcooled blowdown flow rate.

Core collapsed level constitutes a critical quantity during this experiment, as the level variations are directly connected with the occurrence of core dryout. The trend of this variable is strongly affected by the distribution of pressure drops along the loop that also influence the occurrence of threshold phenomena like loop seal clearing.

The calculated core level is in a quite good agreement with the experimental trend (Fig. 12 below and Fig. 15 in App. 2). The first core level depression is not predicted by the code: this discrepancy is connected with the bypass flow paths inside the vessel, that can facilitate the steam discharge form the upper plenum and limit the steam binding effect on the core level. Pumps operation and, in particular, uncertainties in the rotation speed as a function of time and in the head as a function of the rotation speed (homologous curves) can have a role in this connection.

Rod Surface Temperatures

When analyzing the rod surface temperature trends, the three-dimensional situation in the core must be considered, as described into detail in ref. [4].

Representative experimental data at three core levels have been selected for the present comparison, distinguishing in the axial sense, the core bottom, the core middle and the core top regions (Figs. 11 to 13, respectively in App. 2, and Fig. 13 below related to the top region).

Predicted rod surface temperature trends follow well the measured values. The first dryout is not predicted by the code and the reason is connected with the bypass flow paths into the vessel (see above). The second dryout situation is well predicted by the code; it can be noted that, in correspondence of the high core level, the quenching is delayed of about 200 s: minor uncertainties connected with the average power assigned to the involved structure and coming from the position of the thermocouples, can be associated with the considered discrepancy. The occurrence of the final dryout is reasonably well predicted.

4.2.1 Qualitative and quantitative accuracy evaluation

Qualitative accuracy

The qualitative accuracy evaluation here discussed is based upon a systematic procedure consisting in the identification of phenomena (CSNI list) and of RTA. In both cases five levels of judgment are introduced (E, R, M, U, and -) whose meaning is detailed in the notes of Tab. 9 and in App. 1 of ref. [20]. The related results are reported in Tabs. 9 and 10, where for completeness the information related to Relap5/mod2 results are given.

A positive overall qualitative judgment is achieved if 'U' is not present; in addition, the parameters characterizing the RTA (i.e., SVP = Single Valued Parameter, TSE = parameter belonging to the Time Sequence of Events, IPA= Integral Parameter and NDP = Non Dimensional Parameter) give an idea of the amount of the discrepancy.

In the present case the following conclusions could be reached:

a) no 'U' mark is present;
b) all RTA of the experiment are present in the calculated data
c) the accuracy evaluation by adopting RTA and Key Phenomena, supports the conclusion that the calculation is qualitatively correct.

Quantitative Accuracy

The positive conclusion of the qualitative accuracy evaluation, makes it possible addressing the quantitative accuracy evaluation. To this aim a special methodology, developed at University of Pisa, and widely used has been adopted.

The methodology is based upon the use of the Fast Fourier Transform (e.g. ref. [19]); its main features are detailed in App. 1 of ref. [20].

The results of the application of the method are given in Tab. 11, where again the information related to Relap5/mod2 calculation is given too. The conclusions from the quantitative accuracy evaluation analysis are as follows:

a) the achieved results are well below the acceptability threshold both in relation to the overall accuracy (AA = 0.29 compared with the acceptability limit of 0.4) and the primary system pressure accuracy (AA = 0.05 compared with the acceptability limit of 0.1);
b) the achieved results appear slightly better than those obtained by Relap5/mod2.

Definitely, the documented reference calculation is acceptable from the code assessment point of view; i.e. the code is positively assessed in relation to its capabilities to predict this kind of transient.

Tab. 11: Summary of results obtained by application of FFT method to the selected parameters for the reference calculation

4.3 Sensitivity calculations

Considering the extensive sensitivity studies carried out in the frame of the analyses of the Spes tests SP-SB-04 (ref. [20]) and SP-SB-03 (ref. [21]) and the Lobi test BL-34 (ref. [22]) and the acceptable results obtained in the present analysis, it was decided to carry out only two sensitivity studies, focused towards the accumulators behavior and the evaluation of effects of the modeling of the bypass flow paths between the upper head and the downcomer.

The characteristics of the performed calculations can be drawn from Tab. 12, together with the results of the FFT methodology application (overall calculation and primary pressure). The summary of the FFT results related to all the parameters for all the performed sensitivity calculations are given in Tab. 13. The comparison between calculated and measured trends for each sensitivity analysis is reported in Appendix 3 and in Figs. 14 to 17.

As expected, the influence of the performed changes is limited, considering the assigned range of variation of the parameters modified in the analyses; this fact is confirmed by the FFT results (see Tab. 13), that are very similar to those obtained for the reference calculation.

ID Calculation	Variations from reference case	FFT application results (AA_{tot} / WF / AA_P)	Notes
B44F	form loss coefficients in the ACC valve (675) decreased	0.29 / 0.05 / 0.035	to improve the accumulators flow rate, the primary side mass and the prediction of the second dryout
B44L	K_{for} at the core-upper head bypass (430-450) and K_{rev} at the downcomer-upper head bypass (210-440) set equal to 1	0.26 / 0.04 / 0.038	to allow the exit of steam from the break and to improve the primary mass and core temperature prediction

5. CONCLUSIONS

The analyzed transient (BL-44) is a small break LOCA experiment originated by a rupture in the cold leg of the broken loop of the LOBI/MOD2 facility. No high injection system is provided during the test; three dryout situations occur: the first one, at about 189 s into the transient, is quenched by an intrinsic mechanism like loop seal clearing; the second one is quenched by the intervention of the accumulators and the third one is recovered by the actuation of the low pressure injection system.

A qualified Relap5/Mod3.2 nodalization has been used for the analysis. The comparison between the code prediction and the experimental data leads to the conclusion that the code is able to predict all the significant aspects of the transient, with the exception of the first dryout-rewet phenomenon.

The present one constitutes the third of four analyses related to Small Break LOCA having similar characteristics (counterpart tests), e.g. refs. [20] and [21]

Basically, the main conclusions achieved in previous analyses are confirmed by the present one:

- the Relap5/Mod3.2 has full capability in predicting the Relevant Thermalhydraulic Aspects that characterize the transient;
- the above conclusion has been reached following a detailed procedure, including qualitative and quantitative evaluation of accuracy;
- a limited set of sensitivity calculations has been carried out in the present case, considering the reasonable agreement reached in the reference calculation and the results of sensitivity analyses performed and documented in the above mentioned studies: the here considered sensitivity studies do not bring important advances in understanding code capabilities;
- minor discrepancies between measured and calculated trends, judged to be reasonable and acceptable, have been discussed in the text.

LIST OF ABBREVIATIONS

AA	Average Amplitude
ACC	Accumulator
ATWS	Anticipated Transient Without Scram
BL	Broken Loop
CAMP	Code Assessment and Maintenance Program
CCFL	Counter Current Flow Limitation
CSNI	Committee on the Safety of Nuclear Installations
DC	Downcomer
DCMN	Dipartimento Costruzioni Meccaniche e Nucleari
DP	Differential Pressure
ECCS	Emergency Core Cooling Systems
FFT	Fast Fourier Transform
HPIS	High Pressure Injection System
ICAP	International Code Assessment and Application Program
IL	Intact Loop
INEL	Idaho National Engineering Laboratories
IPA	Integral parameter
ISP	International Standard Problem
ITF	Integral Test Facility
$K_{reverse}$	Reverse form loss coefficient
LOCA	Loss Of Coolant Accident
LPIS	Low Pressure Injection System
MFWIV	Main Feed Water Injection Valve
NA	Not Available
NPP	Nuclear Power Plant
NRC	Nuclear Regulatory Commission
PORV	Pressurizer Operated Relief Valve
PRZ	Pressurizer
SG	Steam Generator
SVP	Single Valued Parameter
TSE	Time Sequence of Events
UH	Upper Head
WF	Weighted Frequency

SUBSCRIPTS

A_R	break area
c	core
G_C	overall core inlet flow rate
P_R	break position
RL	recirculation loop
SS.T	mean temperature of secondary side fluid
V	fluid volume
W	core power
WI	total energy supplied by the heater rods

Appendix 1

Steady state calculation

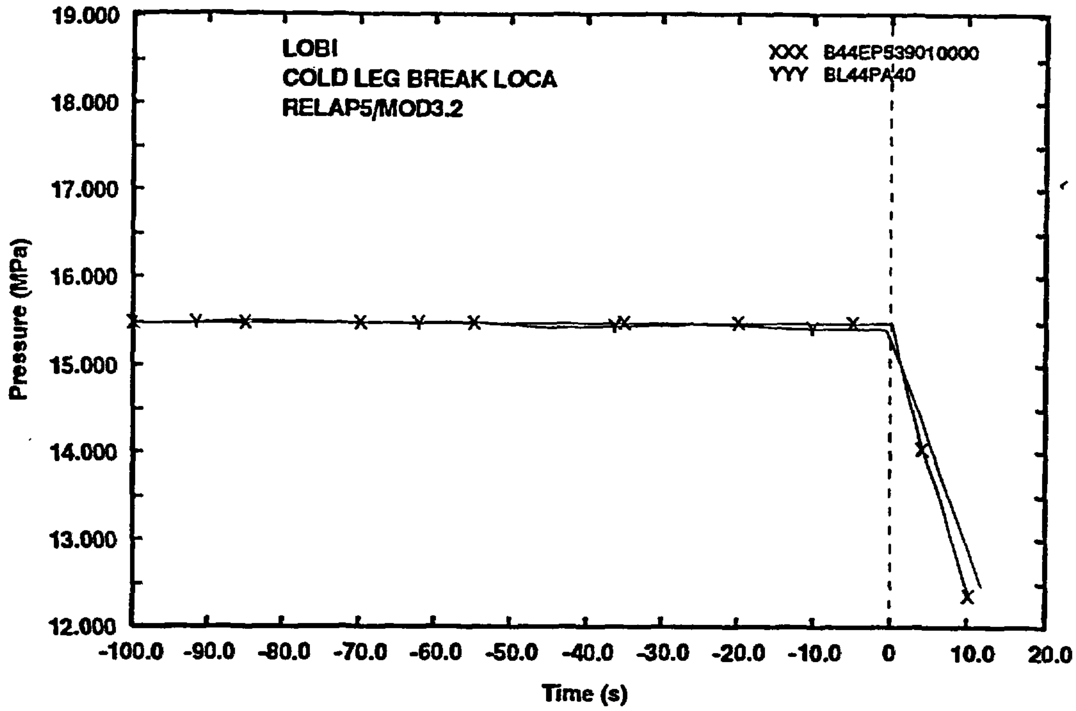

Fig. 1- PRZ pressure

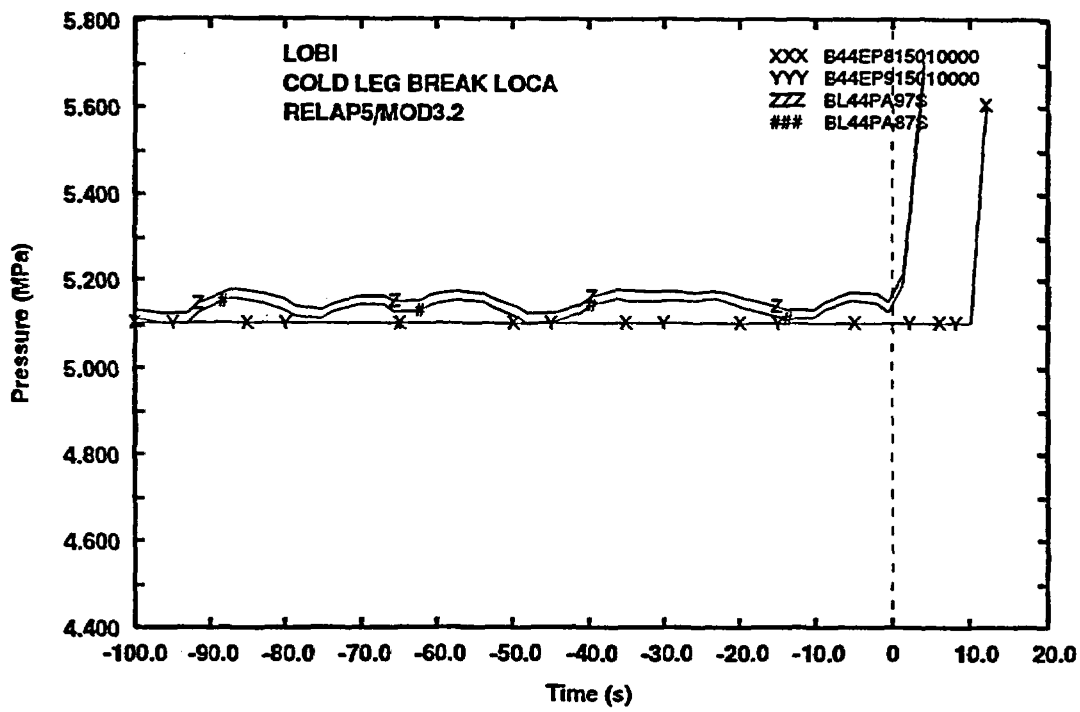

Fig. 2- SGs secondary side pressure

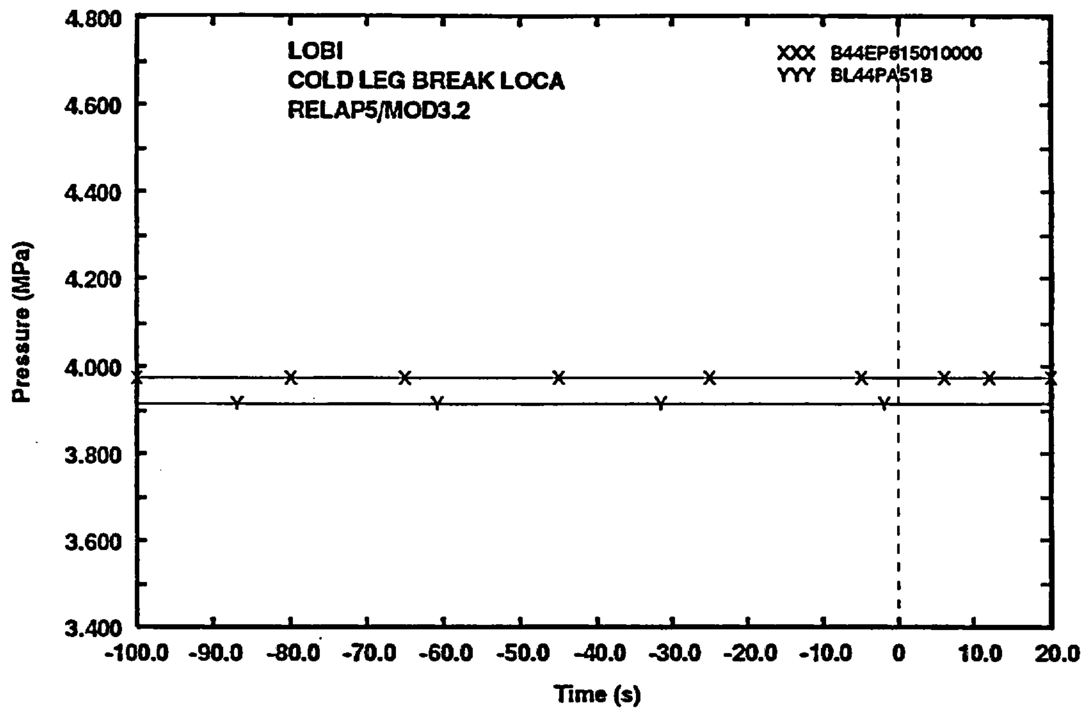

Fig. 3- Accumulator pressure

10. SUPPLEMENTARY NOTES

11. ABSTRACT (200 words or less)

The present document deals with the RELAP5/MOD3.2 analysis of the small break LOCA experiment BL-44 performed in LOBI/MOD2 facility. LOBI/MOD2 was a PWR simulator (Integral Test Facility) installed at JRC Joint Research Center) in Ispra Establishment (I). Volume scaling and core power scaling factors are 1/712, with respect to the KWU Siemens 1300 MWe (3900 MWt) standard reactor. The experiment is originated by a small break in the cold leg (2" equivalent break area in the plant) without the actuation of the high pressure injection system. Low pressure injection system actuation occurs after core dry-out and accumulators intervention is foreseen when primary pressure falls below 4 MPa. The RELAP5 code has been extensively used at University of Pisa; the nodaliztion of LOBI facility has been qualified through the application of the version RELAP5/MOD2 to the same experiment and another test performed in the same facility. Sensitivity analyses have been addressed to the influence of several parameters (like discharge break coefficient, time of accumulators start, etc.) upon the predicted transient evolution. Qualitative and quantitative code calculation accuracy evaluation has been performed.
